ABSTRACT

Citriculture is a growing industry in Pará state, Brazil, but information regarding fruit flies and their associated parasitoids in this region is lacking. To address this gap in knowledge, we collected oranges (*Citrus sinensis*), lime oranges (*C. sinensis*), common sweet limes (*C. limettoides*), citrons (*C. medica*) and mandarins (*C. reticulata*). We recorded field infestation by *Anastrepha obliqua* in *C. sinensis* under natural conditions for the first time in the study region, and a tritrophic relationship between *C. sinensis*, *A. obliqua*, and the parasitoids *Opius bellus* and *Asobara anastrephae* was identified.

KEYWORDS: *Citrus sinensis*, Braconidae, eastern Amazon

Primeiro registro de *Anastrepha obliqua* (Diptera: Tephritidae) e de uma relação tritrófica com parasitoides em um pomar de citros no estado do Pará, Brasil

RESUMO

A citricultura está crescendo no Estado do Pará, Brasil, mas faltam informações sobre as pragas conhecidas como moscas-das-frutas e os parasitóides associados na região. Visando abordar esta lacuna no conhecimento, foram coletados frutos de laranja (*Citrus sinensis*), laranja var. lima (*C. sinensis*), lima-da-pérsia (*C. limettoides*), limão-cidra (*C. medica*) e tangerina (*C. reticulata*). Registrarmos, pela primeira vez, infestação em condições naturais de campo por *Anastrepha obliqua* em *C. sinensis* no Pará e identificamos uma tritrófica entre *C. sinensis*, *A. obliqua* e os parasitóides *Opius bellus* e *Asobara anastrephae*.

PALAVRAS-CHAVE: *Citrus sinensis*, Braconidae, Amazônia Oriental

Pará state is the seventh fruit-producing region in Brazil, with 1.64% of the country's production, constituting one of the largest citrus-producing areas in northern Brazil (Anuário Brasileiro de Fruticultura 2018; IBGE 2019). Citriculture is economically important for the state, and fruit fly infestations, especially by *Anastrepha* species, have been reported (Lemos *et al.* 2011a; Castilho 2013). Fruit flies are considered key pests, and, in most producing regions around the world, sweet oranges and mandarins are highly susceptible to fruit fly infestation (Raga *et al.* 2004; Raga and Galdino 2017). In Brazil, the most important fruit flies belong to the genera *Anastrepha*, *Bactrocera*, and *Ceratitis*. *Ceratitis capitata* (Wiedemann) and *Anastrepha fraterculus* (Wiedemann) are the two main citrus pests in the southeastern state of São Paulo

(Raga *et al.* 2004). In Pará, *C. capitata* have been recorded in mandarin (*Citrus reticulata* Blanco) and *Anastrepha serpentina* (Wiedemann) in *C. reticulata* from Tomé-Açu and *Citrus sinensis* (L.) Osbeck from Belém (Lemos *et al.* 2011b).

Biological control is a promising option for fruit fly control. Natural biological control, focusing on the conservation of natural enemies, is crucial in pest management programs, as these organisms are responsible for natural mortality in agroecosystems and maintenance of the pest balance level (Parra *et al.* 2002). Thus, the identification of potential native agents to control pests in producing regions is vital. The purpose of this study was therefore to identify citrus-infesting fruit flies and their associated parasitoids on small family farms in four municipalities in Pará.

CITE AS: Rodrigues, M.G.; Camargos, M.G.; Alvarenga, C.D.; Silva, R.C.R.; Ayres, Á.R. 2021. First record of *Anastrepha obliqua* (Diptera: Tephritidae) and a tritrophic relation with parasitoids in a citrus orchard in Pará state, Brazil. Acta Amazonica 51: 30-33.

Citrus fruits were collected during irregular visits to four municipalities in northeastern Pará, Capitão Poço, Irituia, Mãe do Rio and Aurora do Pará (Figure 1, Table 1) between January 2018 and January 2019. We collected fruits without larval exit holes and no visible damage from trees and/or on the ground. Sample sizes varied according to fruit availability at the time of the visit. The fruits were transported to the laboratory, where they were counted, weighed, and organized in plastic trays on a thin layer of sterile sand. Fruit fly and/or parasitoid larvae and pupae were quantified per fruit and kept in individualized containers until adult emergence.

Anastrepha species were identified according to the taxonomic keys of Zucchi *et al.* (2011b), and parasitoids were identified according to the taxonomic keys of Canal and Zucchi (2000) and Marinho *et al.* (2011). The voucher specimens of the new associations of hosts and parasitoids were deposited in the entomological collection of Museu de Entomologia Luiz de Queiroz - MELQ (Universidade de São Paulo, campus Escola Superior de Agricultura Luiz de Queiroz - ESALQ) (Table 1).

Overall, 522 fruits were collected, with a combined weight of 57.3kg, among oranges (*Citrus sinensis*), lime oranges (*C. sinensis*), common sweet limes (*Citrus limettiodes* Tanaka), citrons (*Citrus medica* L.), and mandarins (*Citrus reticulata*) (Table 1). We obtained 274 puparia from which 95 insects emerged, 78.9% of which were fruit flies and 21%, parasitoids (Table 1). Most puparia (62.4%) were obtained from oranges, with infestation rates of 2.3 puparia per fruit and 12.6 puparia kg⁻¹ of fruit. The only citrus species free of infestation was citron.

Two fruit fly species were identified: *A. serpentina* and *Anastrepha obliqua* (Macquart). Three females were damaged and therefore the species could not be confirmed (Table 1). *Anastrepha obliqua* was collected only from oranges in Irituia, and this is the first record of *A. obliqua* in oranges in Pará. Irituia was also the only locality where parasitoids were found. Two Braconidae parasitoid species were identified as *Opis bellus* (Gahan) and *Asobara anastrephae* (Muesebeck) (Table 1). No puparia were found in fruits from Aurora do Pará.

Anastrepha serpentina occurs in 20 Brazilian states and is associated with 23 hosts, while *A. obliqua* is associated with 51 hosts across the country. In Brazil, oranges were reported to be infested by *A. serpentina*, *A. obliqua*, *A. fraterculus*, *A. striata* Schiner, *A. turpiniae* Stone, and *C. capitata*, and mandarins by *A. serpentina*, *A. fraterculus*, and *C. capitata* (Zucchi and Moraes 2008). In the Amazon region, *A. obliqua* is distributed in all states, infesting 25 hosts, but no record in *Citrus* had been reported (Zucchi *et al.* 2011a). *Anastrepha serpentina* has only been registered in the Amazonian state Tocantins (Zucchi and Moraes 2008; Zucchi *et al.* 2011a).

In Pará, 23 fruit fly species have been registered, 22 belonging to *Anastrepha* and *C. capitata* (Zucchi and Moraes 2008). The species with the widest distribution in the state are *A. striata*, *A. obliqua*, *A. distincta* Greene, and *A. serpentina* (Lemos *et al.* 2011a). *Anastrepha serpentina* has been reported in oranges (in the municipalities of Belém and Capitão Poço) and mandarins (Tomé-Açu) (Lemos *et al.* 2011b), and *A. obliqua* in Barbados cherries (*Malpighia punicifolia* L.), guavas (*Psidium guajava* L.), jambos (*Syzygium jambos* (L.) Alston), aracá-boi (*Eugenia stipitata* McVaugh), Surinam cherries (*Eugenia uniflora* L.), starfruit (*Averrhoa carambola* L.), yellow

mombin (*Spondias mombin* L.) and coco plums (*Chrysobalanus icaco* L.), in the municipalities of Castanhal, Tomé-Açu, Belém and Ilha de Cotijuba, Baixo Amazonas, and on the Marajó Archipelago (Lemos *et al.* 2011a).

Economically, *A. obliqua* is an important species in Brazil (Zucchi 2007), while *A. serpentina* has not acquired this status. Fruit flies have become a major obstacle in the sustainable development of Amazonian fruit production, as they directly affect the quality of the final product, in addition to preventing products from satisfying the phytosanitary requirements of importing countries (Lemos *et al.* 2011a).

Oranges and mandarins were the most infested fruits in our samples (Table 1), which was expected, as they are highly susceptible to fruit fly infestation (Raga *et al.* 2004; Raga and Galdino 2017). Only citrons were not infested with fruit flies, probably because of their thick flavedo and albedo. The

thickness of the flavedo and albedo layers of lemons, sour oranges (*C. aurantium*), Sicilian lemon (*C. limon*), and citrons (*C. medica*) are greater than those of sweet oranges. This hampers the survival of newly hatched larvae, which need to feed in an unfavorable environment until they reach the juice vesicles (Raga and Galdino 2017). In addition, the variation in fruit fly infestation could be attributed to fruit ripening stages, time and place of collection, seasonal variations, host diversity, and fruit availability (Malavasi *et al.* 1980). Infestation rates in oranges in Pará were considered low in comparison to those in other Brazilian regions (Lemos *et al.* 2011b; Castilho 2013). In another survey in Capitão Poço, average *A. serpentina* infestation rates of 2.28 puparia kg⁻¹ and 0.3 puparia per fruit were reported in oranges (Castilho 2013), which were lower than those reported in here.

Castilho (2013) and Lemos *et al.* (2011b) collected oranges in Capitão Poço and recovered only *A. serpentina* and the parasitoid *Doryctobracon areolatus* (Szépligeti). In addition to *D. areolatus*, *O. bellus* and *Aganaspis pelleranoi* (Brèthes) have been recorded in Pará (Lemos *et al.* 2011a). Our study is the first to record *A. anastrephae* in Pará. A new tritrophic relationship was also identified in Pará for the first time among oranges, *A. obliqua*, and the parasitoids *A. anastrephae* and *O. bellus*. The low number of parasitoids found in our survey was possibly due to low natural occurrence, our small sample size, and use of insecticides in nearby orchards.

The new species records reported in here add to the knowledge on the trophic relationships of the fruit fly complex in citrus orchards in Pará, and can inform future integrated fruit fly management programs in new agricultural frontiers.

ACKNOWLEDGMENTS

We wish to thank Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for the junior postdoctoral (PDJ) and technological and industrial development (DTI) scholarships granted to the authors. We are also grateful to the PhD student Daniel Pereira Soares for support with the maps.
